Quick Start Instructions

Linux-Kit

phyCORE-PXA270

Using Eclipse and the GNU Cross Development Tool Chain

Note: The PHYTEC Linux-phyCORE-PXA270-Disc includes the electronic version of the English phyCORE-PXA270 Hardware Manual.

Edition: October 2009
In this manual copyrighted products are not explicitly indicated. The absence of the trademark (™) and copyright (©) symbols does not imply that a product is not protected. Additionally, registered patents and trademarks are similarly not expressly indicated in this manual.

The information in this document has been carefully checked and is believed to be entirely reliable. However, PHYTEC Messtechnik GmbH assumes no responsibility for any inaccuracies. PHYTEC Messtechnik GmbH neither gives any guarantee nor accepts any liability whatsoever for consequential damages resulting from the use of this manual or its associated product. PHYTEC Messtechnik GmbH reserves the right to alter the information contained herein without prior notification and accepts no responsibility for any damages that might result.

Additionally, PHYTEC Messtechnik GmbH offers no guarantee nor accepts any liability for damages arising from the improper usage or improper installation of the hardware or software. PHYTEC Messtechnik GmbH further reserves the right to alter the layout and/or design of the hardware without prior notification and accepts no liability for doing so.

Chapter 1 Introduction

In this Quick Start you can find general information on the PHYTEC phyCORE-PXA270, and an overview of the Eclipse software development tool and the GCC C/C++ cross development tool chain. You will also find instructions on how to run example programs on the phyCORE-PXA270, mounted on the PHYTEC Development Board, in conjunction with the Eclipse development tool.

Please refer to the phyCORE-PXA270 Hardware Manual for specific information on board-level features, such as jumper configuration, memory mapping, and pin layout.

1.1 Rapid Development Kit Documentation

This “Rapid Development Kit” (RDK) includes the following electronic documentation on the enclosed “PHYTEC Linux-phyCORE-PXA270-Disc:”

- The PHYTEC phyCORE-PXA270 Hardware Manual.
- PXA270 Controller User's Manuals and Data Sheets.
- This Quick Start Instructions with general “Rapid Development Kit” description, software installation advice, and an example program enabling quick out-of-the-box start-up of the phyCORE-PXA270 in conjunction with the Eclipse and GCC C/C++ software development tool chain.
1.2 Professional Support Packages Available

This kit comes with free installation support. If you have any questions concerning installation and setup, you are welcome to contact our support department.

For more in-depth questions, we offer a variety of custom-tailored packages with different support options (e-mail, phone, direct contact to the developer) and different reaction times.

Please contact our sales team to discuss the appropriate support option if professional support beyond installation and setup is important to you.

1.3 Overview of this Quick Start Manual

This Quick Start manual gives you a general “Rapid Development Kit” description, as well as software installation advice and an example program enabling quick out-of-the-box start-up of the phyCORE-PXA270 in conjunction with the Eclipse IDE and GCC C/C++ software tools. It is structured as follows:

- The “Getting Started” chapter describes the configuration of the host platform and how to setup all the tools used in this manual.

- The “Getting More Involved” chapter provides step-by-step instructions on how to configure and build a new kernel, modify an example application, create and build new projects, and copy programs to the phyCORE-PXA270 using Eclipse.

- The “Debugging” chapter provides information on how to debug an application with the Eclipse debugging interface.

In addition to the dedicated data for this Rapid Development Kit, the PHYTEC Linux-phyCORE-PXA270-Disc contains supplemental information on embedded microcontroller design and development in general.
1.4 Conventions Used in this Quick Start Manual

The following is a list of the typographical conventions used in this Quick Start manual:

*Italic* Used for file and directory names, program and command names, command-line options, menu items, URLs, and other terms that correspond the terms on your desktop.

*Bold* Used in examples to show commands or other text that should be typed literally by the user.

Pay attention to notes set apart from the text with the following icons:

- **OPTION**
  At this part you might leave the path of this Quick Start.

- **CAUTION**
  This is a warning. It helps you to avoid annoying problems.

- **TIP**
  Provides useful supplementary information about the topic.

- **TIME**
  At the beginning of each chapter you can find information of the time needed to pass that chapter.

- **SUCCESS**
  You have successfully passed an important part of this Quick Start manual.

- **RESOLVE**
  Provides information to solve common problems.
1.5 System Requirements

Use of this “Rapid Development Kit” requires:

- The PHYTEC phyCORE-PXA270.
- The PHYTEC Development Board with the included DB-9 serial cable, Ethernet cross-over cable and AC adapter supplying 12 VDC (min. 2 A).
- PHYTEC Linux distribution based on OSELAS from Pengutronix.
- An IBM-compatible host PC (586 or higher CPU).
- openSUSE 11.0 (x86) and the KDE desktop.
- Recommended free disk space: at least 2 GB.

For more information and updates, please refer to the following sources:

http://www.phytec.de
support@phytec.de
1.6 Software Development Tool Chains

1.6.1 Eclipse

The Eclipse platform provides support for C/C++ development. Because the Eclipse platform is only a framework for developer tools, it doesn't support C/C++ directly; instead it uses external plug-ins. This Quick Start shows you how to make use of the CDT, a set of plug-ins for C/C++ development in conjunction with the GCC C/C++ tool chain.

The CDT is an open source project (licensed under the Common Public License) implemented purely in Java as a set of plug-ins for the Eclipse SDK platform. These plug-ins add a C/C++ perspective to the Eclipse Workbench that can now support C/C++ development with a number of views and wizards, along with advanced editing and debugging support.

Due to its complexity, the CDT is broken down into several components, which take the form of separate plug-ins. Each component operates as an autonomous project, with its own set of committers, bug categories, and mailing lists. However, all plug-ins are required for the CDT to work properly. Here is a list of the plug-ins/components:

- **Primary CDT plug-in** is the “framework” for the CDT plug-ins.
- **CDT Feature Eclipse** is the CDT Feature Component.
- **CDT Core** provides Core Model, CDOM, and Core Components.
- **CDT UI** is the Core UI, views, editors, and wizards.
- **CDT Launch** provides the launch mechanism for external tools such as the compiler and debugger.
- **CDT Debug Core** provides debugging functions.
- **CDT Debug UI** provides the user interface for the CDT debugging editors, views, and wizards.
• **CDT Debug MI** is the application connector for MI-compatible debuggers.

### 1.6.2 The GNU Cross Development Tool Chain

Cross development in general refers to the overall software development process that produces a single application or a complete system running on a platform that is different from the development platform. This is an important concept when the target system doesn’t have a native set of compilation tools, or when the host system is faster and has greater resources.

The platform where the actual development takes place is called the *host platform*. The platform where the final application is tested and run is called the *target platform*. In this Quick Start we are using an x86-based Linux as the host platform. As the target platform we are using the ARM architecture with an PXA270 CPU.

Building a program for a CPU architecture different from the one used on the machine where the compilation is done is accomplished using a cross compiler tool chain and cross-compiled libraries. In this Quick Start we are using the GNU C/C++ cross development tool chain.
Chapter 2 Getting Started

In this chapter you will establish the basis to pass the steps in this Quick Start. First you will learn how to configure the host platform. You will install additional software packages and setup the network configuration for connecting your host to the target. After connecting the host to the target, you will copy an application to the target. At the end of this chapter you will be able to start a first demo application on the target.

2.1 Requirements of the Host Platform

To pass the following steps in this Quick Start, you will need a host PC with an installation of openSUSE 11.0 (x86) and the KDE desktop.

When you are installing openSUSE 11.0, you can select KDE as Desktop selection. The default packages to use openSUSE 11.0 with your host PC will be selected automatically. This default selection will suffice to pass the steps in these Quick Start Instructions. The installation of additional packages and configurations will be described on the following pages.

In the following configuration steps we assume that the host PC is not connected to any other network. The target and host will be connected with a cross-over cable via a peer-to-peer connection. If your host is part of a company’s network, we recommend disconnecting your host from such a network.

In these Quick Start Instructions you will have to shutdown the firewall and configure the network card of your host PC. If your host PC is connected to another network, changing the IP address can cause conflicts with existing hosts.
2.2 Configuring the Host Platform

In this passage you will learn how to configure the host platform. You will execute the following steps:

- Install additional software packages. These packages are necessary to accomplish the steps in the Quick Start Instructions.
- Set up the network configuration to use the host PC with your target.
- Disable the firewall. If the firewall is enabled, you will have problems with connecting to the target.
- Set up a TFTP server. You can use a TFTP server to download files (e.g. kernel and root file system images) to the target from within the target’s boot loader.

2.2.1 Installing Software Packages

To accomplish the steps in the Quick Start Instructions, you will have to install additional packages.

If you don’t install all of these packages, the setup may fail or some configuration steps won’t work correctly.
• Open the *K menu* from the lower-left corner of the desktop and click on the tab *Computer*.

• Open the *Administrator Settings / YaST*.

• Enter your root password and click *OK*.
• Open **Software Management** in **Software**.

• Select the filter **Search**.

• Type **libxml2-devel** and click the **Search** button.

• Check **libxml2-devel**.
• Type **python-devel** and click the *Search* button.

• Check **python-devel**.

• Type **tftp** and click the *Search* button.

• Check the packages **tftp** and **yast2-tftp-server**.
Type `qt3-devel` and click the *Search* button.

Check `qt3-devel`.

Select the filter *Patterns*.

Select *Basis Development*, *C/C++ Development*, and *Tcl/Tk Development*.

Click *Accept*. 
Some additional packages will be selected automatically to resolve any dependencies.

If problems occur while resolving dependencies, we recommend going back to a default configuration.

- Click **Continue** to install the packages.

- Click **Finish**.
2.2.2 Set Up Network Card Configuration

In the following steps you will have to configure the IP address of your host. We recommend disconnecting your host from any other network. If you change the host’s IP, chances are that problems may occur with other hosts in the network.

- Open the *YaST Control Center* if it is not already opened.

- Choose *Network Settings* in *Network Devices*. 
Select the right network card (if more than one network card is installed on your host).

Click *Edit* to enter the *Network Card Setup*.

Choose *Static address setup*.

Enter IP address *192.168.3.10* and subnet mask *255.255.255.0*

### 2.2.3 Disabling the Firewall

To ensure that there are no problems with connections to the target, the host’s firewall should be disabled.

Select the *General* tab in the upper-left corner.
• Use the drop-down box in the Firewall Zone settings to set the current interface to Internal Zone (Unprotected).

• Then press Next, and in the following window click Finish to complete the settings.

The firewall is now disabled for this network card.

2.2.4 Set Up TFTP Server

Later in this Quick Start you will learn how to write a new kernel image into the flash memory of the target. To download the kernel image from the target, you need to have a TFTP server running. In this passage we show you how to configure a TFTP server.

• Open the YaST Control Center if it is not already opened.
• Choose **TFTP Server** in **Network Services**.

![YeST Control Center](image)

If the **TFTP Server** icon does not exist, restart the YaST Control Center.

• Switch the selection to **Enable**.

• The path of the boot image directory should be **/tftpboot**. If there is a different path, change it to **/tftpboot**.

• Click **Finish**.
Click *Yes* to create the `/tftpboot` directory.

The TFTP server will be started.

- Close the YaST Control Center.

*You have successfully finished the configuration of the host platform.*

### 2.3 Linux-phyCORE-PXA270-Kit Setup

In this section you will find a description of the Linux-phyCORE-PXA270-Kit setup. The whole setup will be done by a graphical interface. At the end of the setup you will find all programs to develop applications for the target on your host PC.

The setup will install the following programs:

- **GNU C/C++ cross development tool chain** – you can use this tool chain to develop programs for the target on your host PC.

- **Eclipse SDK with CDT** – the Eclipse SDK is a platform and application framework for building software which can use the GNU C/C++ cross development tool chain.

- **Microcom** – a program for serial communication with the target.

- **Linux Kernel archive** – this kernel archive contains the Linux kernel source code as well as all patches needed to compile the kernel for the phyCORE-PXA270.
**HelloWorld** – this example program can be used to test how to download and execute a program on the target.

**mkimage** – this program will be used to create the kernel image file for the target.

There will be some additional configuration steps performed on your PC:

- The setup program will create desktop links to the installed programs.
- The setup will also create desktop links to access the target via FTP, SSH, and Telnet.
- The path of the cross development tool chain will be added to the $PATH environment variable.
- Read and write access to the serial interface will be added to your user account so you use the serial communication program Microcom.
- The setup will configure Microcom.

### 2.3.1 Starting the Setup

To start with the Linux-phyCORE-PXA270-Kit setup, put your PHYTEC Linux-phyCORE-PXA270-Disc into your CD-ROM drive.

The following dialog may appear:

- Click *Cancel*. 

• From the *K menu*, select the *Applications* tab.

• Select *System* ▶ *Terminal* ▶ *Terminal Program / Konsole*.

• Type: `cd /media/SO-450`

• Enter `.install.sh` to launch the setup program.
The media may be mounted on a different mount point in the directory `/media`. The mount points can be shown with the command `ls /media`. Change to the accordant directory if no directory `SO-450` should exist.

- Enter the root password.

- Click `Yes` to proceed.

  The welcome screen appears.
• Click Next to continue.

• Click Next.
Click *Next* to copy all files to your hard disk.

The default destination location is `/usr/local/share/phyCORE-PXA270-Kit`. All path and file statements within this Quick Start manual are based on the assumption that you accept the default installation paths. If you decide to individually choose different paths, you must consider this for all further file and path statements when working with this Quick Start.

We strongly recommend accepting the default destination location.
The GCC C/C++ tool chain will be installed to the default directory `/opt/OSELAS.Toolchain-1.99.3/arm-iwmmx-linux-gnueabi`. The program `mkimage` will be installed to `/usr/local/bin`. All other programs and examples will be installed to the selected destination directory.

After the files have been copied, a dialog box for the Eclipse installation will appear.

- Click Yes to install Eclipse. If you want to skip the installation of Eclipse, choose No.
We recommend installing Eclipse even if you already have installed Eclipse on your system. The version of Eclipse provided on the setup CD-ROM includes additional plug-ins.

Click Next.

Installation Eclipse

Click yes to install Eclipse. The Eclipse Development Platform will be installed. This installation contains the C/C++ Development Tools plugin.

The time of the installation depends on your host platform.

When the installation finished, you can choose next to proceed the setup.
• Click *Finish* to exit the setup.

• Close the terminal window.

Now you will have to restart the KDE desktop.
Open the *K Menu* from the lower-left corner of the desktop.

Select the *Leave* tab and choose *Logout*.

When the display manager appears, enter your login name and password to restart the KDE desktop.

You have successfully installed the software for the Linux-PXA270-Kit. You can now use the programs you need to develop your own applications for the target on your host system. The setup program did all necessary configurations. In the following passage you can find some advanced configuration information.

### 2.4 Advanced Configuration Information

In this part you can find some information on how to change the configuration steps of the setup program by your own. The setup program performed all the following configuration steps. The information in this
part is for users who want to use the PXA270-Kit with a Linux distribution other than openSUSE. This is also interesting for users who want to see what configurations the setup program did.

During the setup program, the GCC C/C++ cross compiler was installed in the directory 

```
/opt/OSELAS.Toolchain-1.99.3/arm-iwmmx-linux-gnueabi/gcc-4.3.2-glibc-2.8-binutils-2.18-kernel-2.6.27-sanitized/bin.
```

To start the cross compiler directly from every location of the system, the directory of the cross compiler was added to the $PATH environment variable. You can manually add the directory of the cross compiler to the $PATH by adding the following line in the file `/etc/profile`:

```bash
export PATH=/opt/OSELAS.Toolchain-1.99.3/arm-iwmmx-linux-gnueabi/gcc-4.3.2-glibc-2.8-binutils-2.18-kernel-2.6.27-sanitized/bin:“$PATH”
```

You can open a terminal program and use the cross compiler directly from the command line. For example, you can compile a C program with the following command:

```bash
arm-iwmmx-linux-gnueabi-gcc -o HelloWorld HelloWorld.c
```

In the standard configuration only the root user has write access to the serial interface. To use a serial communication tool like Microcom with normal user rights, you have to be a member of the group `uucp`. A user can be added to this group with the following command:

```
groupmod -A username uucp
```

The serial communication program was configured during the setup with the following configuration:

```
115200 baud, 1 start bit, 8 data bits, 1 stop bit, no parity, no flow control.
```
2.5 Connecting the Host with the Target

In this section you will learn how to connect your host PC with the target. The connection will be done using a cross-over Ethernet cable and a serial one-to-one cable. You will start Linux from flash on the target, and you will be able to login with the serial communication program Microcom as well as via a Telnet session using a peer-to-peer network connection.

- Connect the serial cable with the UART1 (connector P1) port on the target and the first serial interface on your host.

  Ensure to use the one-to-one serial cable included in this Rapid Development Kit.

- Connect the cross-over Ethernet cable with the RJ45 connector of the target and the appropriate network card of your host.

  ![Microcom](image)

- Click the Microcom icon on your desktop.

- Connect the AC adapter with the power supply connector X1 (12V) on your board.

  The power connector should have 12 VDC inside, and outside should be ground.

After connecting the board with the power supply, the target starts booting. When the target has finished loading the system, you should see a screen similar to the following:
- Type root to login.
- After you have successfully logged in, you can close Microcom.

If you don’t see the U-Boot and Linux starting and don’t get a login prompt, you probably have a kit with Windows CE preinstalled. Please refer to the chapter “Writing the kernel into the Targets’ Flash” for instructions on how to install Linux in such a case.

When the target is connected with the power supply, first the boot loader U-Boot is loaded from the flash memory. Then the boot loader is uncompressing and booting the Linux kernel from the flash. The kernel will then mount the root file system, which is also located in the target’s flash. The root file system uses the Journaling Flash File System, Version 2.

JFFS2 is the successor, and a complete rewrite, of the original JFFS by Red Hat. As its name implies, the JFFS2 implements a journaling file system on the memory technology device (MTD) it manages. JFFS2 does not attempt to provide a translation layer that enables the use of a traditional file
system with the device. Instead, it implements a log-structured file system directly on the MTD. The file system structure itself is recreated in RAM at mount time by JFFS2 through a scan of the MTD’s log content.

In addition to its log-structured file system, JFFS2 implements wear levelling and data compression on the MTD it manages, while providing power-down reliability. JFFS2 can gracefully restart, and is capable of restoring a file system’s content, without requiring outside intervention regardless of power failures.

Troubleshooting:

If you don’t see any output in the Microcom window, check the serial connection between the target and your host.

At the end of the setup, you had to restart the KDE desktop. If you haven’t done yet, restart the KDE desktop now and try again.

It is also possible that your user account is missing read and write access to the serial interface:

- Open the YaST Control Center.
- Choose Security and Users.
- Choose User Management.

In the line of you user name should be the group uucp.

- If the group is missing, select your user name and click the Edit button.
- Select the tab Details.
- In Groups, check the group uucp.
• Click *Accept*.

• Click *Finish* and close YaST.

• You need to log out and log in again for the new group membership to take effect.

Now you can test the network connection to the target.

A new window with a connection to the target opens.

If you can see the user login in the opened window, the network configurations were configured correctly.

• Close the window.
**Troubleshooting:**

If you don’t see the user login, check the connection between the target and the host. If you have installed more than one network card on your host, be sure to connect the cable with the network card you have configured with the IP address 192.168.3.10.

If you do not see the login, you may not have set up the right IP address of your host. You can check the settings of your network card by opening YaST. In the YaST Control Center you can select *Network Settings* in *Network Devices*. There should be the following configuration:

![Network Configuration](image)

Information on how to configure your network device can be found in the section *Configuring the Host Platform*.

You have successfully set up all configurations to access your phyCORE-PXA270 from your host.

### 2.6 Copying an Example to the Target

In this section you will learn how to copy an example program to the target using the FTP protocol with the *Konqueror* browser. After that you will execute the example on the target. At the end of this passage you can find some information on how to copy and execute a file on the target using the command line.
2.6.1 Copying a Program to the Target

- First click the *phyCORE-PXA270-Kit* icon on your KDE desktop.
  
  A new window with the contents of the installation directory opens.

- Enter the directory *HelloWorld*.

- Click the *FTP for Target* icon on your desktop.
A window with an FTP session to the target opens. Now you have two windows opened, one for the target and one for the host. You can use these two windows to copy files per “drag and drop” from the host to the target (and vice versa).

- Select the window that lists *HelloWorld* program on your hard disk.
- Click the *HelloWorld* program and hold the left mouse button pressed.
- Drag the program into the window with the FTP session to the target and release the mouse button.
- Choose *Copy here* in the appearing context menu.
- Close the two windows.

### 2.6.2 Using Telnet to Execute a Program on the Target

- Click the *Telnet for Target* icon on your KDE desktop.
Enter **root** as login and press **Enter**.

Enter `/HelloWorld` and press **Enter**.

The program starts and you should see the following output:

```
Welcome to the World of the phyCORE-PXA270!
```

### 2.6.3 Using SSH to Execute a Program on the Target

SSH can be used if you want to execute a program directly from the host on the target. Later, this will be used to execute programs out of Eclipse on the target. Before you can start programs out of Eclipse, you have to log in to the target via SSH from the command line for one time. This is necessary to add the RSA public key of the target to the list of known hosts.

There are several authentication methods when using SSH. The method used on the phyCORE-PXA270 is the `hosts.equiv` method combined with RSA-based host authentication.

If the machine the user logs in from is listed in `/etc/hosts.equiv` on the remote machine, and the user name is the same on both sides, the user is allowed to log in.
On the target, the file `/etc/hosts.equiv` has the following entry:

```plaintext
# file: /etc/hosts.equiv
#
# Allow access from everywhere.
#
+ +
```

The “+ +” means that every user can log in from every host.

When the host connects to the target, the file `~/.ssh/known_hosts` (on the host) is consulted when using `hosts.equiv` with RSA host authentication to check the public key of the target. The key must be listed in this file to be accepted. When the host connects to the target for the first time, you will be asked to store the target’s RSA public key to your `~/.ssh/known_hosts`. If you agree to do this, then the host will be able to connect to the target without entering a password.

This authentication method closes security holes due to IP spoofing, DNS spoofing, and routing spoofing. But note that `/etc/hosts.equiv` is, in general, inherently insecure and should be disabled if security is a concern.

- Click the `SSH for Target` icon on the desktop.

  A new window opens.
In this window you can see that the authenticity of the phyCORE-PXA270 can’t be established. This is normal if you want to create an SSH connection for the first time.

- Enter yes and press Enter to continue. The RSA public key of the target will be permanently added to the list of the known hosts.

**Troubleshooting:**

If an error occurs and you can’t see the root@phyCORE:~> prompt, open a terminal window and enter the following command:

- rm ~/.ssh/known_hosts

Try to log in again by entering:

- ssh root@192.168.3.11

- Enter yes to add the target to the list of known hosts.

Now you should see the target’s prompt.

We expect that you haven’t changed the SSH configuration file on your host. If you change this file, the authentication may not work.
Now you are logged in, you can execute programs on the target.

- Type `.HelloWorld` to start the program you had copied to the phyCORE-PXA270 before.

  The program starts and you should see the following output:

  
  Welcome to the World of the phyCORE-PXA270!

- Close the SSH window.

You have successfully copied and executed an example application on the target.

## 2.7 Advanced Information

### 2.7.1 Copying a Program to the Target with the Command Line

- Open a new terminal window.
- Change to `/usr/local/share/phyCORE-PXA270-Kit/HelloWorld`:

```
  cd /usr/local/share/phyCORE-PXA270-Kit/HelloWorld
```

- Copy the application to the target by typing:

```
  ftp -u ftp://root:root@192.168.3.11/ HelloWorld
```

  Be sure to enter a slash followed by a space after the IP address.

### 2.7.2 Executing a Program on the Target

- Open a Telnet session to the target:

```
  telnet 192.168.3.11
```

- Type `root` and press Enter.
- Type `.HelloWorld` to start the application.
2.7.3 Executing a Program directly on the Target using SSH

- To start the program, type:
  \[
  \text{ssh root@192.168.3.11 ./HelloWorld}
  \]
  
  After the program has finished, SSH will logout automatically.
Chapter 3 Getting More Involved

In this chapter you will pass some continuative topics. First you will configure and compile your own kernel. With the kernel configuration tool you can add additional features, or disable them if they are not needed. After compiling the kernel, you will learn how to write the newly created kernel into target’s flash memory and how to start the new kernel.

Then you will start working with the Eclipse platform using the C/C++ Development Tools (CDT) in conjunction with the GCC C/C++ tool chain. You will learn how to configure the Eclipse platform and how to open an existing project. After that you will create your first own project and modify the example’s source code.

At the end of this chapter you will execute the program as an external application out of Eclipse. Additionally, you will add your application to the startup configuration of the target so it is automatically started when the phyCORE-PXA270 boots.

3.1 Configuring and Compiling the Kernel

In this part you will learn how to configure and build a new Linux kernel. First you will copy the kernel archive to your home directory and extract the kernel source. Then you will configure the kernel with the graphical user interface qconf. After the configuration you will compile the new kernel using the GNU cross development tool chain.

The kernel used by PHYTEC is based a standard kernel available from www.kernel.org. Additionally, the kernel archive in your setup installation directory already includes all necessary patches for the phyCORE-PXA270.

As the first step, open a new terminal.
• Click the terminal icon on your desktop.

• Type the following commands to copy the kernel archive to your home directory:

```
cp /usr/local/share/phyCORE-PXA270-Kit/linux-*PCM027.tar.bz2 ~
cd ~
```

• Unpack the kernel source archive:

```
tar xvjf linux-*-PCM027.tar.bz2
```

• Change to the newly created directory:

```
cd linux-*
```

The kernel would normally be built for the native machine architecture of your host. To use the ARM architecture and ARM cross compiler suitable for the phyCORE-PXA270 instead, you will have to specify the architecture and the cross compiler on the command line.

• Type:

```
make xconfig ARCH=arm
```

The kernel configuration tool qconf starts.
Select **I2C support** in **Device drivers**.

- Check **I2C support**.
- Check **I2C device interface**.
- Save your configuration and exit the configuration tool.
- Type:

  ```
  make ARCH=arm CROSS_COMPILE=arm-iwmmx-linux-gnueabi- uImage
  ```

The kernel sources will be compiled and the new kernel will be built. This will take a few minutes. The new kernel will be written to `arch/arm/boot/uImage`.

If the process of building the kernel stops with an error, check the values of both **ARCH** and **CROSS_COMPILE**.

- Close the terminal window.
In this section you learned how to configure and compile a new kernel. Now you can add new features to your kernel, or remove features you do not need.

3.1.1 Writing the Kernel into the Target’s Flash

In this passage you will find a description how to write the newly created kernel into the flash memory. Before the kernel can be written into flash, you will have to download the kernel from a tftp server. This will be done in the command line of the bootloader. The kernel will be copied into RAM, starting at address 0x400000. Then you will have to erase the part of the FLASH, where you want to copy the Kernel image.

In the default configuration you will find three partitions on the target. The first partition contains the boot loader, the second the Kernel and the third contains the root file system.

The three partitions have the following address ranges:

- 0x00000000 - 0x0003FFFF: U-Boot (256k)
- 0x00040000 - 0x0023FFFF: Kernel (2048k)
- 0x00240000 - 0x11FFFF: Root-Filesystem (30464k)

You should never erase the U-Boot partition. If this partition is erased, you can’t restart your target.
• First open a new terminal window if it is not opened yet.
• Copy the new kernel image to the /tftpboot directory and exit:

```bash
cp ~/linux-*/arch/arm/boot/uImage /tftpboot; exit
```

• Open Microcom and press the RESET button on the target.
  You will see the output “Hit any key to stop autoboot.”
• Press any key to stop autoboot.

![Microcom Output](image)

You can download the kernel from the TFTP server to the target’s RAM, erase the required flash area, and write the kernel from the RAM into the flash with just one simple command: `run update_kernel`. 
- Type the following command to set the name of your kernel image:
  
  ```
  setenv kernel uImage
  ```

- Type `run update_kernel` to download and write the kernel into the Flash.

  The copy process can take up to a minute, depending on the speed of your system.

- Press the RESET button on the target to restart the phyCORE-PXA270 with the new kernel. The target will boot the newly created kernel.

- Close Microcom when the target has successfully finished with booting the kernel and mounting the root file system.
Troubleshooting:
If any problem occurs after writing the kernel into Flash, you can write the kernel and root-file system from your setup CD into the Flash.

You can find the kernel and root file system in the directory Linux\image.
To restore your system copy the files uImage-pcm027 and root-pcm027.jffs2 into the directory /tftpboot

Type the following commands in the u-boot command line
setenv kernel uImage-pcm027-x
setenv rootfs root-pcm027-x.jffs2
run update_kernel
run update_rootfs

In this section you learned how to download a kernel image from a TFTP server into the RAM of the target. The kernel was written from RAM to flash, and finally the target was started with the new kernel.

3.2 Opening an Existing Project

In this section you will import an existing Eclipse project into your workspace. The imported example project will be compiled with the cross compiler. After compiling the project, you will copy and execute the newly created program on the target.
3.2.1 Copying the *HelloWorld* Project

- Click the *phyCORE-PXA270-Kit* icon on your KDE desktop.
- Right-click the *HelloWorld* directory and select *Copy*.
- Browse to your home directory.
- If the *workspace* directory doesn’t exist, create a directory *workspace* in your home directory.
- Enter the *workspace* directory.
- Right-click in the *workspace* directory and select *Paste*.

3.2.2 Starting Eclipse and Importing the Example Project

- Click the *Eclipse* icon to start the application. You can find this icon on your desktop.
• Confirm the Workspace directory with OK.

The *Welcome* screen will appear.

• Select *File ➤ Import* from the menu bar.
• Select *Existing Projects into Workspace*.

• Click *Next*.

• Select *Browse*.
• Double-click the *HelloWorld* directory in your home directory.

• Click *OK*.

• Select *Finish* to import the project.
• Close the *Welcome* screen.

The *HelloWorld* program will be compiled and the *HelloWorld* executable is built for the target. Then the *HelloWorld* file is copied to the target using FTP. After the file has been copied to the target, the program is executed on the target using SSH. You should now see the “*Welcome to the World of the phyCORE-PXA270!*” message in the *Console* window.

• Select the *Console* tab.

You will see the following content in the *Console* window:
If the project is not built automatically, you will have to check Project ► Build automatically from the menu bar.

You have successfully passed the first steps with the Eclipse IDE. You are now able to import existing projects into the Eclipse Workspace. You can compile an existing project and execute the program on the target.

3.3 Creating a New Project

In this section you will learn how to create a new project with Eclipse and how to configure the project for use with the GNU C/C++ cross development tool chain.

- Open Eclipse if it isn’t already opened.
- Select File ► New ► Project from the menu bar.
  A new dialog opens.
• Select *Managed Make C Project* and click *Next*.

• Enter the project name *myHelloWorld* and click *Next*. 
- Click Next.

- Click Finish.
• Select Yes to open the C/C++ perspective.

You will see the C/C++ IDE with the myHelloWorld project.
• Right-click on HelloWorld.c in the HelloWorld project which we have worked with previously.

• Select Copy.

• Select the myHelloWorld project.

• Right-click and select Paste.

• Double-click on HelloWorld.c in the myHelloWorld project.
If Build Automatically from the Project menu is selected, the HelloWorld application will now be compiled and created with the standard GCC C/C++ compiler suitable for your host machine. You will find the executable file, which can only be run on your host system, in the workspace/myHelloWorld/Debug directory.

To compile your project for the phyCORE-PXA270 instead, you will have to use the GNU C/C++ cross compiler.

- Right-click the myHelloWorld project and choose Properties.

The Properties dialog appears.

- Select C/C++ Build.

- Enter arm-iwmmx-linux-gnueabi-gcc into the Command input field.
• Select **GCC C Linker**.

• Enter **arm-iwmmx-linux-gnueabi-gcc** into the *Command* input field.

• Select **GCC Assembler**.

• In the *Command* input field, change the default as to **arm-iwmmx-linux-gnueabi-as**.

• Click *Apply*.
• Select the *Build Steps* tab.

• Enter following command in the *Command* input field:

```sh
cmd = ftp -u ftp://root:root@192.168.3.11/ ./myHelloWorld ;
ssh root@192.168.3.11 ./myHelloWorld
```

Be sure to enter the semicolon between `./myHelloWorld` and `ssh`.

**CAUTION**

Be sure the file *myHelloWorld* on the target will have execution rights, because otherwise `ssh` will fail.

• Click *Apply*.

• Click *OK*.
Select Project ► Clean from the menu bar.

Confirm with OK.

The project will be rebuilt.

Select the Console tab.

If no errors occur while building the project, you will see the following output:

You have successfully created your first own project with the Eclipse IDE. You have configured the project to create an application for your target platform.
3.4 Changing the Demo Application

Now we will extend the *myHelloWorld* application. The extended *myHelloWorld* application will write an output to the first serial interface as well as the standard output.

- Open Eclipse if it is not opened yet.
- Double-click *HelloWorld.c* in the *myHelloWorld* project.
- First include the following two additional header files:
  ```c
  #include <unistd.h>
  #include <fcntl.h>
  ```
- Then add the function `write_tty()`, which writes \( n \) bytes to the first serial interface (which, on the phyCORE-PXA270, is connected to the system console `/dev/console`):
  ```c
  void write_tty(char *buffer, int count)
  {
      int out;

      out = open("/dev/console", O_RDWR);
      write(out, buffer, count);
      close(out);
  }
  ```
- Enter the following two lines in the `main()` function to declare the buffer and call the `write_tty()` function.
  ```c
  char buf[] = { "Welcome to the World of the phyCORE-PXA270! (serial)\n               "};
  write_tty(buf, sizeof(buf) - 1);
  ```

In the next screenshot you can see the complete program.
Save your program after changing the code.

The application will be compiled, built, copied to the target, and executed.

3.4.1 Executing the Program on the Target using Microcom

- Click the Microcom icon on the desktop.
- If you are not logged in, enter root and press Enter.
- Type ./myHelloWorld to start the application.
- You will see the following output:
  
  Welcome to the World of the phyCORE-PXA270! (serial)
  Welcome to the World of the phyCORE-PXA270!

- Close Microcom.
When you start the application over an SSH session, you only see one output line. When you execute the program with Microcom, you see two output lines.

The first line is a direct output on the serial interface. You can’t see this line in an SSH session, because you are connected over a TCP/IP connection to the target. With Microcom, however, you have direct access to serial interface, so you can also see the line that it written to the serial console.

In this passage you have changed an existing application. You also learned how to access the serial interface. First you called the function `open()` on the device `/dev/console`. The return value of this function was a file descriptor. With the file descriptor you called the function `write()` to send \( n \) bytes to the device `/dev/console`. After that, the file descriptor was closed with the function `close()`.

This procedure is in principle quite typical for Linux because Linux treats everything like a file.

### 3.5 Starting a Program out of Eclipse on the Target

After compiling a project in Eclipse, the program is copied to the target and directly executed. A program can also be executed on the target without compiling a project. In the following section you will learn how to start a program on the target as an external tool.
• Select Run ▶ External Tools ▶ External Tools from the menu bar.

• Select Program.

• Select New.
In the Name input field, enter: **myHelloWorld Target**

Enter `/usr/bin/ssh` in the Location input field.

Enter `root@192.168.3.11 ./myHelloWorld` into the Arguments field.

Select Apply.

Select Run.

If you want to execute the program the next time, you can use the Run External Programs button from the menu bar.
3.6 Automatically Starting the Program when Booting the Target

In this passage you will integrate the *myHelloWord* program into the startup process of the target. When you have finished this part, the *myHelloWorld* application will be started automatically each time you are starting the target.

The scripts for controlling the system startup live in `/etc/init.d`. These are executed directly or indirectly by `/sbin/init`, the father of all processes. The configuration of `/sbin/init` is placed in `/etc/inittab`.

After system startup, `/sbin/init` will switch to the default run level, as configured in `/etc/inittab`. It calls the run level master script `/etc/init.d/rcS` to start or stop services provided by the other scripts in `/etc/init.d`. This is done by the help of symbolic links in the directory `/etc/rc.d`. These links point to the actual startup scripts in `/etc/init.d`.

First you will have to create a startup script in `/etc/init.d`.

- Click the *FTP for Target* icon on your KDE desktop.
• Browse to the target’s /etc/init.d. If an authorization dialog should appear, just click on OK (no password is required for FTP access).

In the directory /etc/init.d you can see the existing scripts.

• Right-click in the opened window and select Create New ► Text File.

• Enter myHelloWorld.

• Click OK.

• Right-click on myHelloWorld and select Open with.

• Enter kwrite and click OK.
The text editor *KWrite* starts with an empty document.

- Enter the following two lines:

```bash
#!/bin/sh
/home/myHelloWorld
```

- Select *File ▶ Save*.

- Close the *KWrite* window.

- Close the *FTP* window.

- Click the *Telnet for Target* icon on your desktop.
Enter root and press Enter to login.

The startup script we have just created with KWrite must be made executable in order to run it later:

```bash
chmod a+x /etc/init.d/myHelloWorld
```

• Change to the directory /etc/rc.d. Type the following command:

```bash
cd /etc/rc.d
```

• Enter `ls -l` to list the directory contents.

You can see the different links to the scripts in the directory /etc/init.d. The scripts are started in alphabetic order: The script `udev` is the first script started because the link starts with `S00...`, whereas `S99zzz_PHYTEC_BSP_version_startup_script` will be started last.

To start your `myHelloWorld` application automatically when the system boots, you have to create a new link to the start script /etc/init.d/myHelloWorld.

• In /etc/rc.d, create a symbolic link which points to /etc/init.d/myHelloWorld. Enter the following command:

```bash
ln -s /etc/init.d/myHelloWorld /etc/rc.d/S99myHelloWorld
```

• Type `ls -l` again to check the newly created link.
• Close the window.

• Open Microcom.

• Push the RESET button on the target to restart your system.

The program `myHelloWorld` now starts automatically on startup. Because its link in `/etc/rc.d` starts with `S99...`, you should see `myHelloWorld`'s output near the output of the two other scripts that start with `S99...` (which print all sorts of version information).

• Close Microcom.
Now you can add your own programs to the root file system and start these programs automatically when your phyCORE-PXA270 boots.

You have successfully passed the “Getting More Involved” part of this Quick Start.
Chapter 4 Debugging an Example Project

In this chapter you will learn using the GNU debugger, GDB, on the host for remote debugging in conjunction with the GDB server on the target. GDB is the symbolic debugger of the GNU project and is arguably the most important debugging tool for any Linux system.

First you will start the GDB server on the target. Then you will configure the Eclipse platform and start the GNU debugger out of Eclipse using the Debug view.

The CDT extends the standard Eclipse Debug view with functions for debugging C/C++ code. The Debug view allows you to manage the debugging and running of a program in the Workbench. Using the Debug view you will be able to set breakpoints/watchpoints in the code and trace variables and registers. The Debug view displays the stack frame for the threads of each target you are debugging. Each thread in your program appears as a node in the tree, and the Debug view displays the process for each target you are running.

The GDB client is running on the host and is used to control the GDB server on the target, which in turn controls the application running on the target. GDB client and GDB server can communicate over a TCP/IP network connection as well as via a serial interface. In this Quick Start we will only describe debugging via TCP/IP.

4.1 Starting the GDB Server on the Target

In this passage you will learn how to start the GDB server on the target. The GDB server will be used to start and control the myHelloWorld program.
To debug a program with GDB, the program needs extended debugging symbols. With the default Eclipse settings, these debugging symbols have already been added when building the program.

- Open Microcom.

- Type `root` and press Enter.
- Start the GDB server:

  ```
  gdbserver 192.168.3.11:10000 myHelloWorld
  ```

You have started the GDB server on the target. The GDB server is now waiting for connections on TCP port 10000.
4.2 Configuring and Starting the Debugger in Eclipse

In this passage you will learn how to configure your project settings to use Eclipse with the GNU debugger. After the configuration of your project settings, the GNU debugger will start and connect to the GDB server on the target.

- Start Eclipse if the application is not started yet.
- Select *myHelloWorld* in the **Navigator** window.
- Select **Run ➤ Debug** from the menu bar.

A dialog to create, manage, and run applications will appear.

- Select **C/C++ Local Application**.
- Click **New**.
Select the Search Project button.

Click OK.
Select the Debugger tab.

Select GDB Server from the Debugger drop-down box.

Click the Browse button right beside the GDB debugger input field. A new dialog opens to choose the GDB executable.

Click on File System.

Navigate to the directory /opt/OSELAS.Toolchain-1.99.3/arm-iwmmx-linux-gnueabi/gcc-4.3.2-glibc-2.8-binutils-2.18-kernel-2.6.27-sanitized/bin.

Select the file arm-iwmmx-linux-gnueabi-gdb.

Click OK.
From the *Connection* drop-down box, select *TCP*.

Enter **192.168.3.11** (the target’s IP address) in the *Host name* input field. The host’s GDB will connect to this IP address to communicate with the target’s GDB server.

- Click *Apply*.
- Click *Debug*.
  
  A new dialog appears.
• Select Yes to switch to the Debug perspective.

The Debug perspective opens and the debugger stops at the first line automatically. The host’s GDB is now connected to the GDB server on the target.
You have configured your project for remote debugging. You have started the GNU debugger in Eclipse and connected the host’s GDB with the target’s GDB server. You can now start to debug the project.

4.3 Setting a Breakpoint

Now you will set a breakpoint in your program. The breakpoint will be set on the last line. If you resume the application, the debugger will stop on this line.

- Select the last line in `main()`.
- Right-click into the small grey border on the left-hand side and select `Toggle Breakpoint` to set a new breakpoint.
4.4 Stepping and Watching Variable Contents

In this part you will step through the example project with the debugger. You will also learn how to watch the content of a variable.

- Expand `buf` in the `Variables` window.

![Variables Window](image)

- Click on the `Step Over` button in the `Debug` window to step to the next line.

  You will see the content of the `buf` variable in the `Variables` window.

- Click on the variable `buf`.

![Code Window](image)

- Then click on the button `Step into` to enter the function `write_tty()`.

  The debugger stops in `write_tty()`.

  You will see the following variable window:
• Click on the variable buffer.

You will probably see a different address at the buffer pointer. Remember what address is shown in your case; you will need this address later.

### 4.5 Changing Variable Values

In this section you will change the value of a variable. At the end of this part you will see the effect of this change.

• Select the count variable in the Variables window.

• Right-click on count and select Change Value.
- Change the value of count to 7 and click OK.
- Open Microcom if the application is not already opened.
- Go back to Eclipse.
- Click the Step Over button two times.
- Change to Microcom.

You will see the output Welcome in the Microcom window. This means that due to changing the counter variable's value, instead of printing the full “Welcome to the World of the phyCORE-PXA270” string, only the first seven characters of the buffer were written to the screen.

### 4.6 Using the Memory Monitor

In the last section of this chapter you will use the memory monitor to watch the content at a memory address.
• Select the Memory tab.

• Click Add Memory Monitor.

• Enter the address of buffer and click on OK. Remember that the variable’s address might differ on your system.

• Change the window size.
• Click *Add Rendering*.

![Add Memory Rendering dialog]

- Select *ASCII* and click *OK*.

![Memory Monitor window with variable contents]

You can see the contents of the variable *buffer* at the address 0xbeda6e48 (or whatever address is used on your system).

• Now click the *Resume* button from the menu bar.
The debugger stops at the breakpoint in the last line of `main()

- Click the Resume button to end the application.

You have successfully passed the debugging chapter. You are now able to configure and use Eclipse for remote debugging. You can step through a project, watch and change the content of variables, and you can use the memory monitor to view the content at a memory address.
Chapter 5 Further Information

In the PTXdist User Manual you can find further information. The manual is located on your setup CD-ROM in the directory:

```
PHYTEC/PCM027 phyCORE-PXA270/Linux-Kit/BSP/OSELAS
```

The PTXdist User Manual includes information on the following topics:

- Installation and Configuration of PTXdist.
- Building and using a tool chain.
- Create and activate a PTXdist project.
- Running the phyCORE-PXA270 from network only.
- Running the phyCORE-PXA270 stand-alone.
- U-Boot on the phyCORE-PXA270.
- The phyCORE-PXA270’s Board Support Package (BSP).
- Using CAN on the phyCORE-PXA270.
Chapter 6 Summary

This Quick Start manual provided a general “Rapid Development Kit” description, as well as software installation advice and an example program enabling quick out-of-the-box start-up of the phyCORE-PXA270 in conjunction with the Eclipse IDE and GNU C/C++ software tools.

In the Getting Started section you learned how to configure your host to provide a basis for working with your target platform. You installed the Rapid Development Kit software and learned how to copy and run a program on the target.

In the Getting More Involved section you got step-by-step instructions on how to configure and build a new kernel, modify the example application, create and build new projects, and copy programs to your phyCORE-PXA270 using Eclipse.

The Debugging part of this Quick Start gave you information on setting up and using the GNU debugger with the Eclipse IDE. You learned how to set breakpoints, watching and changing variable contents, and using the memory monitor.
Chapter 7 Installing Linux on the phyCORE-PXA270

This part provides instructions on how to install the boot loader (U-Boot) on the phyCORE-PXA270 and how to write a kernel and/or a root file system image into the target’s flash memory.

7.1 Installing the Boot Loader

The boot loader used on the phyCORE-PXA270 is U-Boot, the Universal Boot Loader. The installation of the boot loader will be performed by jflash. To run jflash, you will have to use a host running Microsoft Windows.

- Insert your PHYTEC Linux-phyCORE-PXA270 -Disc, navigate to the PHYTEC\PCM027 phyCORE-PXA270\Linux-Kit\Software\Tools\jflash directory.
- Navigate to the directory jflash\giveio.
- If you are using Windows NT run loaddrv2_NT.exe. If you are using Windows XP run loaddrv2_XP.exe.
- A dialog opens:

![LoadDrv dialog](image)

- Select install.

The driver will be installed and started.
• Click on Button OK.

After you have installed the giveio driver, connect the jtag interface of your board with the jtag adapter and connect the jtag adapter with a parallel cable. Plug the cable into the interface LPT1 on your host.

Now you can use jflash to write the bootloader to flash.

• Connect the AC adapter with the power supply connector X1 (12V) on your board.

**Note:** The power connector should have 12 VDC inside and outside should be ground.

• Navigate to the folder jflash.

In this folder you can find the batch file prog.bat.

• Double-click on prog.bat

• A new window opens.

• Press Enter for two times to start writing the bootloader into flash.
After writing, jflash starts verifying. There will be some verifying errors. These errors can be ignored.

- Disconnect the power supply of the target.

**Note:** After installing the bootloader you have to disconnect the target of the power supply before you can start the target.

### 7.2 Configure U-Boot Environment Variables

The following steps will be done on a Linux platform. We assume that you have configured your host platform and have executed the setup program provided on the Linux-phyCORE-PXA270-Disc. Information on how to configure the host platform can be found in the *Getting Started* part of this Quick Start.

- Connect the serial cable with the UART1 (connector P1) on the target and the first serial interface on your host.

- Connect the cross-over Ethernet cable with the connector X23 on the target and the right network card of your host.

- Click the *Microcom* icon on your desktop

Microcom was configured during the setup with the following configuration:

*115200 baud, 1 start bit, 8 data bits, 1 stop bit, no parity, no flow control.*

If you want to use a program other than Microcom for serial communication, you will have to setup that program with these settings.
• Connect the AC adapter with the power supply connector X1 (12V) on your board.

• Press any key to stop autoboot.

If no default configuration can be found in the EEPROM, the built-in configuration will be used, and you will see the following line:

*** Warning - bad CRC, using default environment.

Enter the following command to setup the MAC-address of your target. The MAC address can be found on the phyCORE module.

• Type `setenv ethaddr <mac-address>`

  for example: `setenv ethaddr 00:50:C2:52:9E:3D`

• Enter `saveenv` to save the environment settings to the EEPROM.

The default ip address of the target is 192.168.3.11 and the default server ip is 192.168.3.10. If you want to setup another network configuration, you can use the following commands:

  setenv ipaddr <target ip>
  setenv serverip <server ip>
  setenv gateway <gateway ip>
  setenv netmask <netmask>

7.3 Restore the U-Boot default configuration

If you want to restore to the default configuration you can uses the following command to delete the configuration in the EEPROM:

• `eeprom write 0 0 10`

After pressing the reset button, the default configuration of the bootloader will be used.
Configure the MAC address with the following command:

- `setenv ethaddr <mac-address>`
- Typ `saveenv` to store the settings in the EEPROM

### 7.4 Writing the Kernel / Root File System into Flash

Before the kernel / root file system can be written into flash, you will have to download the image from a tftp server. This will be done in the command line of the bootloader. First the image will be copied into RAM. Then you will have to erase the part of the FLASH, where you want to copy the Kernel image.

In the default configuration you will find three partitions on the target. The first partition contains the boot loader, the second the Kernel and the third contains the root file system.

The three partitions have the following address ranges:

- `0x00000000 - 0x0003FFFF`: U-Boot (256k)
- `0x00040000 - 0x0023FFFF`: Kernel (2048k)
- `0x00240000 - 0x01FFFFFF`: Root-Filesystem (30464k)

In the directory BSP/Images on your PHYTEC Linux-XScale-Disc you can find a file uImage-pcmXXX-Y. This file is the kernel image. There is another file root-pcmXXX-Y.jffs2. This file contains the root file system.

- Copy the files uImage-pcmXXX_Y and root-pcmXXX_Y.jffs2 into the directory /tftpboot

You can download the kernel / root file system from the TFTP – server, erasing the required Flash area and writing the kernel from the RAM into the Flash with one simple command.

Before you can execute this command you have to set the name of your kernel image to the environment variable `kernel` and the name of jffs2-file to the variable `rootfs`.

- Open Microcom if is not opened.
• Type the following commands in the u-boot command line to set the environment variables:

```plaintext
setenv kernel uImage-pcmXXX_Y
setenv rootfs root-pcmXXX_Y.jffs2
```

• Then you can start downloading and writing the kernel image into the Flash.

• Type run update_kernel.

```
Uboot> run update_kernel
Using MAC Address 00:50:22:5A:70:6C
TFTP from server 192.168.3.10, our IP address is 192.168.3.11
Filename 'uImage-pcm027_pcm990'.

Erase Flash Partition nor0,1, bank 0, 0x00000000 - 0x00003fff done
Erased 16 sectors
Copy to Flash... done
Uboot>
```

• Type run update_rootfs to download and write the root file system into the flash.

• Press the RESET button on the target to start your target.

The target will start with the kernel and root file system you have written into the Flash.
